

(a) Spacing decides ghost collisions

a ghost returns at $\tau_a - \tau_b + \tau_c$

uniform spacing: every ghost lands on a grating

10 ghost paths return inside the array, 10 on a grating

randomized spacing: almost none does

9 ghost paths return inside the array, 1 on a grating

delay bin τ (grating position)

(b) Side-lobe leakage, $K = 32$
